

## Problem statement:

Create a program which will **count the number of words** in any text file. By definition, a “word” is a sequence of characters separated by white space; white space is blanks, tabs, grammatical symbols ( ? ( ) . “ etc ) and end of line characters.

## Code:

A sample text file is provided (“**wake.txt**”).

Download and copy the sample text file in your working drive and then write the program that opens the file (“**wake.txt**”), reads all the words from the sample file and write the count of words to an output file named “**out.txt**”

While opening the file, browse to the file location :

**Example:** `ifstream inFile ;`

`inFile.open( “file path listed here”);`

Use the same approach for writing to the **out.txt** file, that is, the result of running the program should be written to a file and **NOT** the console.

## Submission Guidelines:

Browse to your **Lab Submissions** module in course tab **CS 121**

- Upload the source code **Lab7.cpp** and the **text file** containing the screen capture of the output window.
- Submit hardcopies of the source code of Lab7.cpp and text file containing screen capture in class.
